CSC 360 Activity #1

1. This paper was written 10 years ago. However, the authors mentioned some statistics about software failures, such as 49% of software experiencing budget overruns, 47% with higher than expected maintenance costs, and 41% failing to deliver the expected requirements. Are these statistics still valid, especially considering the significant improvement in technology and AI? Can you find a research paper that supports your opinion? Please cite the paper you find. Use Google Scholar or the Quincy University Library engine to look for research papers. I think that this data still holds validity during this current time. Although there have been advancements in technology and AI , the paper mentions that there are always going to be issues when it comes to technology. And, that is unfortunately true even when constant advancements are made towards technologies. I will also mention that the certain statistics on what kind of failures are present in the development of software still holds validity as well. Software is a constant process as the demands of society change regardless of how perfect it may be. Unfortunately, I was not able to find a research paper regarding my opinion since most of the research papers talked about what kind of failures were still present in software engineering rather than an article that aligned with my opinion.
2. What case study do you find most interesting or surprising?

I think Case 3.2 with the destruction of the Ariane 5 rocket was the most surprising to me because of the amount of things lost. There wasn't anyone on the rocket, but the satellites that took 10 years to make were destroyed in the explosion as well as costing the ESA \$100 million in losses. What is the most interesting is the fact that the explosion went off because of a single line of code! When I saw that, it just went to show how crucial every line of code is in a program since it can cause the destruction of others, a company, etc.

3. What questions do you still have after reading the paper?

I personally have no questions regarding the paper. I think that the paper did a good job in presenting how often software does fail and it is still valid even now as well as going over events/software to show how important it is.
